ABSTRACT

Twenty fish and one lamprey species were recorded from 14 rivers of the catchment areas of the Stobrawa and Smortawa (mid- Odra basin, SW Poland). The ichthyofauna of both those catchment areas is quantitatively poor and at present consists of psammophilous and phytophilous species of short life cycles, small size and low economic importance. Such a situation results from the regulation and pollution of most rivers led to disappearance of species of economic or angling importance.
